<b>Purpose</b>	Once coagulants are added and mixed, heavy particles in the water begin to stick together and form large and heavy flocs.	Flocculants are added to accelerate settling of the flocs. These large particles are removed by scrapers. The water passes through media based filters for further turbidity reduction.	Chlorine Dioxide and/or Chlorine are added to treated water to control microbiological growth. Untreated water with microbial load can cause various problems.	Chemicals are added to control corrosion, scale, deposition and biological fouling in heat transfer equipment. Chemical dosing is automated by dosing skids. Blow down water is passed through filters for re-use in cooling towers.	Improved efficiency is achieved through use of corrosion and scale control chemicals in boilers. Feed water quality of high purity is obtained through DM plants. Condensate polishers enable water re-use.	Process side water generally needs to be of a particular quality. This quality is obtained by treating the water through equipment. RO membranes need to be clean and scale free to maintain throughput.	Microbial cultures help break down complex chemical pollutants and reduce pollution load. Aeration is very important to provide oxygen for break down activity. Coagulants help form large flocs.	Foul odor is an often neglected problem in ETP's. Enzymes are safe to use odor control products. Flocculants accelerate settlement of flocs and their transfer to sludge tank. Filters further reduce turbidity.	Chlorine Dioxide and/or Chlorine are added to treated water to control microbiological growth. Untreated water with microbial load can cause various problems.
